Introduction

Quantum threat: Shor's quantum algorithm can break integer factorization and discrete logarithm in polynomial time

PQC: Algorithms are currently under standardization with several international initiatives

Importance: These new algorithms will be implemented securely in a variety of use cases

Banking

Personal Data

Communication

ML-DSA draft specification is derived from Version 3.1 of **CRYSTALS-Dilithium** (Dilithium)

CRYSTALS-Dilithium is the main PQC signature algorithm, selected in 2022 by the NIST

Our Contribution: Template based exploitation of intermediate value on Dilithium

Dilithium

- **Dilithium**: public key signature algorithm
- Based on hard problems on Lattices
 - M-LWE
 - M-SIS
- Three security levels: Dilithium-2, Dilithium-3, Dilithium-5
- Two versions: deterministic and randomized
- Recommended as principal PQC signature scheme:
 - > Adjusting security levels is simple
 - > Minimal `pk` size + `sign` size
 - > Already some constant time properties
- **Advantage**: No known efficient algorithm, classical or quantum, can solve these problems in less than exponential time

Attack path

From the verification algorithm: $2 w'_1 := \text{UseHint}_q(h, Az - ct_1 2^d, 2\gamma_2)$

Suppose an attacker has access to several signatures $\sigma = (c, z, h)$

$$\begin{aligned} Az - ct_1 2^d &= A(y + cs_1) - c(A s_1 + s_2 - t_0) \\ &= \underbrace{Ay}_w - cs_2 + ct_0 \\ &= w_1 2\gamma_2 + w_0 + c(t_0 - s_2) \end{aligned}$$

- Assuming an attacker is able to distinguish when $(w_0)_i = cst$ then

$$(Az - ct_1 2^d)_i = (w_1)_i 2\gamma_2 + cst + (c(t_0 - s_2))_i \quad (1)$$

Repeat for all the $k \times n$ coefficients

Attack path

- $t_0 - s_2$ allows us to find s_1

$$A s_1 + s_2 = t_1 2^d + t_0$$

$$A s_1 = t_1 2^d + (t_0 - s_2)$$

A is not square, but $(A^t A)$ is square and invertible with high probability

$$s_1 = (A^t A)^{-1} A^t (t_1 2^d + (t_0 - s_2)) \quad (2)$$

- Knowing s_1 suffices to sign arbitrary messages

Remark: The attack's efficiency depends on how well we can differentiate for $(w_0)_i = 0$

Template Attack (TPA) in theory

TPA are a powerful type of Side Channel Attacks

Step 1:

Record many power traces using different keys and inputs

Step 2:

Create a template by selecting points of interest

Step 3:

Record few power traces using multiple plaintexts

Step 4:

Apply the template to the attack traces

- ANOVA used to select the POIs and 5 peaks kept as POIs to build the template

OPEN

Matching Phase (Step 3 and 4):

Figure: Matching value for LSB 0

Figure: Matching value for LSB 1

- 0 value clearly distinguishable from the rest, even with 1 trace

Definition (False positives - False negatives)

False positives: predicting $w_0 = 0$ while it's not

False negatives: predicting $w_0 \neq 0$ while it's not

- **fp:** 0.067% $\Rightarrow \leq 1$ coeff from the $k \times n$
- **fn:** 0.174% \Rightarrow more signatures to acquire

- Same results for ≈ 100 first coeffs

OPEN

Filtering w_0 for efficiency

SCA measurements might be imperfect:

- **False positives** impact the success rate of the attack
- **False negatives** impact only the number of signatures needed
- We propose a filter on public values to avoid introducing equations with false positives

$$|(Az - ct_1 2^d - w_1 2\gamma_2)_{i,j}| \leq 2\sqrt{\frac{2^{2d} - 1}{12}}\tau$$

Discard \approx **70%** of the $k \times n$ coeffs where we might not have $(w_0)_i = 0$ (impact on **fp**)

However \approx **5%** of true $w_0 = 0$ are erroneously removed (impact on **fn**)

Countermeasures

Goal: Reduce the potential leakage spots

Simple countermeasures are known and efficient against this attack

- Shuffling of coefficient during sensitive steps ([Decompose](#) and [Subtraction](#))
- Secret sharing/ Masking when manipulating w_0
 - Masking design of the [Decompose](#) function discussed in [ACNS2019, CHES2023, CHES2023]
 - For the [Subtraction](#) use masked $r_0 = \text{LowBits}_q(w - c \cdot s_2, 2 \gamma_2)$

Conclusion

To summarize, this work on Dilithium signature:

- First exploitation of a zero value leakage on w_0 during signature execution
- In turn, allows to recover s_1 , and then forge signatures
- Shows that the leakage can be exploited in practice through experimentations
- Discusses Filtering, Resolution and Error Management steps for efficiency
- Highlights simple known countermeasures

Future work on evaluating the impact of noise on error management tools
